1 236299 - Introduction to Natural Language Processing

1.1 Project 4: Semantic Interpretation – Question Answering

The goal of semantic parsing is to convert natural language utterances to a meaning representation such as a *logical form* expression or a *SQL query*. In the previous project segment, you built a parsing system to reconstruct parse trees from the natural-language queries in the ATIS dataset. However, that only solves an intermediary task, not the end-user task of obtaining answers to the queries.

In this final project segment, you will go further, building a semantic parsing system to convert English queries to SQL queries, so that by consulting a database you will be able to answer those questions. You will implement both a rule-based approach and an end-to-end sequence-to-sequence (seq2seq) approach. Both algorithms come with their pros and cons, and by the end of this segment you should have a basic understanding of the characteristics of the two approaches.

1.2 Goals

1. Build a semantic parsing algorithm to convert text to SQL queries based on the syntactic parse trees from the last project.
2. Build an attention-based end-to-end seq2seq system to convert text to SQL.
3. Improve the attention-based end-to-end seq2seq system with self-attention to convert text to SQL.
4. Discuss the pros and cons of the rule-based system and the end-to-end system.
5. (Optional) Use the state-of-the-art pretrained transformers for text-to-SQL conversion.

This will be an extremely challenging project, so we recommend that you start early.

2 Setup

[89]:
```
import copy
import datetime
import math
import re
import sys
```

```
import warnings
from pathlib import Path

import wget
import nltk

```

3 Semantically augmented grammars

In the first part of this project segment, you'll be implementing a rule-based system for semantic interpretation of sentences. Before jumping into using such a system on the ATIS dataset – we'll get to that soon enough – let's first work with some trivial examples to get things going.

The fundamental idea of rule-based semantic interpretation is the rule of compositionality, that *the meaning of a constituent is a function of the meanings of its immediate subconstituents and the syntactic rule that combined them.* This leads to an infrastructure for specifying semantic interpretation in which each syntactic rule in a grammar (in our case, a context-free grammar) is associated with a semantic rule that applies to the meanings associated with the elements on the right-hand side of the rule.

3.1 Example: arithmetic expressions

As a first example, let's consider an augmented grammar for arithmetic expressions, familiar from lab 3-1. We again use the function `xform.parse_augmented_grammar` to parse the augmented grammar. You can read more about it in the file `scripts/transform.py`.

[93]:
```
arithmetic_grammar, arithmetic_augmentations = xform.parse_augmented_grammar(
    """
    ## Sample grammar for arithmetic expressions

    S -> NUM                                : lambda Num: Num
```

```
      | S OP S                              : lambda S1, Op, S2: Op(S1, S2)

    OP -> ADD                               : lambda Op: Op
        | SUB
        | MULT
        | DIV

    NUM -> 'zero'                           : lambda: 0
         | 'one'                            : lambda: 1
         | 'two'                            : lambda: 2
         | 'three'                          : lambda: 3
         | 'four'                           : lambda: 4
         | 'five'                           : lambda: 5
         | 'six'                            : lambda: 6
         | 'seven'                          : lambda: 7
         | 'eight'                          : lambda: 8
         | 'nine'                           : lambda: 9
         | 'ten'                            : lambda: 10

    ADD -> 'plus' | 'added' 'to'            : lambda: lambda x, y: x + y
    SUB -> 'minus'                          : lambda: lambda x, y: x - y
    MULT -> 'times' | 'multiplied' 'by'     : lambda: lambda x, y: x * y
    DIV -> 'divided' 'by'                   : lambda: lambda x, y: x / y
    """
)
```

Recall that in this grammar specification format, rules that are not explicitly provided with an augmentation (like all the `OP` rules after the first `OP -> ADD`) are associated with the textually most recent one (`lambda Op: Op`).

The `parse_augmented_grammar` function returns both an NLTK grammar and a dictionary that maps from productions in the grammar to their associated augmentations. Let's examine the returned grammar.

[94]:
```
for production in arithmetic_grammar.productions():
  print(f"{repr(production):25}     {arithmetic_augmentations[production]}")
```

```
S -> NUM                  <function <lambda> at 0x7f5a7cbdf4c0>
S -> S OP S               <function <lambda> at 0x7f5a7cbdf700>
OP -> ADD                 <function <lambda> at 0x7f59b4075af0>
OP -> SUB                 <function <lambda> at 0x7f59b4075160>
OP -> MULT                <function <lambda> at 0x7f59b40758b0>
OP -> DIV                 <function <lambda> at 0x7f59b4075940>
NUM -> 'zero'             <function <lambda> at 0x7f59b40751f0>
NUM -> 'one'              <function <lambda> at 0x7f59b40754c0>
NUM -> 'two'              <function <lambda> at 0x7f59b4075310>
NUM -> 'three'            <function <lambda> at 0x7f59b4075550>
NUM -> 'four'             <function <lambda> at 0x7f59b4075ca0>
```

```
NUM -> 'five'                <function <lambda> at 0x7f59b4075f70>
NUM -> 'six'                 <function <lambda> at 0x7f59b4075e50>
NUM -> 'seven'               <function <lambda> at 0x7f59a81740d0>
NUM -> 'eight'               <function <lambda> at 0x7f59a8174040>
NUM -> 'nine'                <function <lambda> at 0x7f59a8174280>
NUM -> 'ten'                 <function <lambda> at 0x7f59a8174430>
ADD -> 'plus'                <function <lambda> at 0x7f59a81744c0>
ADD -> 'added' 'to'          <function <lambda> at 0x7f59a81745e0>
SUB -> 'minus'               <function <lambda> at 0x7f59a8174550>
MULT -> 'times'              <function <lambda> at 0x7f59a8174670>
MULT -> 'multiplied' 'by'    <function <lambda> at 0x7f59a8174700>
DIV -> 'divided' 'by'        <function <lambda> at 0x7f59a81743a0>
```

We can parse with the grammar using one of the built-in NLTK parsers.

[95]:
```
arithmetic_parser = nltk.parse.BottomUpChartParser(arithmetic_grammar)
parses = [p for p in arithmetic_parser.parse(
    'three plus one times four'.split())]
for parse in parses:
    parse.pretty_print()
```

```
            S
        ____|_________
       S         |    |
   ____|____     |    |
  S    OP   S    OP   S
  |    |    |    |    |
 NUM  ADD  NUM  MULT NUM
  |    |    |    |    |
three plus one times four
```

```
            S
   _________|____
  |    |         S
  |    |     ____|____
  S    OP   S    OP   S
  |    |    |    |    |
 NUM  ADD  NUM  MULT NUM
  |    |    |    |    |
three plus one times four
```

Now let's turn to the augmentations. They can be arbitrary Python functions applied to the semantic representations associated with the right-hand-side nonterminals, returning the semantic representation of the left-hand side. To interpret the semantic representation of the entire sentence (at the root of the parse tree), we can use the following pseudo-code:

```
to interpret a tree:
    interpret each of the nonterminal-rooted subtrees
```

```
    find the augmentation associated with the root production of the tree
        (it should be a function of as many arguments as there are nonterminals on the right-ha
    return the result of applying the augmentation to the subtree values
```

(The base case of this recursion occurs when the number of nonterminal-rooted subtrees is zero, that is, a rule all of whose right-hand side elements are terminals.)

Suppose we had such a function, call it `interpret`. How would it operate on, for instance, the tree `(S (S (NUM three)) (OP (ADD plus)) (S (NUM one)))`?

```
interpret (S (S (NUM three)) (OP (ADD plus)) (S (NUM one)))
    |->interpret (S (NUM three))
    |      |->interpret (NUM three)
    |      |      |->(no subconstituents to evaluate)
    |      |      |->apply the augmentation for the rule NUM -> three to the empty set of valu
    |      |      |      (lambda: 3) () ==> 3
    |      |      \==> 3
    |      |->apply the augmentation for the rule S -> NUM to the value 3
    |      |      (lambda NUM: NUM)(3) ==> 3
    |      \==> 3
    |->interpret (OP (ADD plus))
    |      |...
    |      \==> lambda x, y: x + y
    |->interpret (S (NUM one))
    |      |...
    |      \==> 1
    |->apply the augmentation for the rule S -> S OP S to the values 3, (lambda x, y: x + y), a
    |      (lambda S1, Op, S2: Op(S1, S2))(3, (lambda x, y: x + y), 1) ==> 4
    \==> 4
```

Thus, the string "three plus one" is semantically interpreted as the value 4.

We provide the `interpret` function to carry out this recursive process, copied over from lab 4-2:

[96]:
```
def interpret(tree, augmentations):
    syntactic_rule = tree.productions()[0]
    semantic_rule = augmentations[syntactic_rule]
    child_meanings = [interpret(child, augmentations)
                      for child in tree
                      if isinstance(child, nltk.Tree)]
    return semantic_rule(*child_meanings)
```

Now we should be able to evaluate the arithmetic example from above.

[97]:
```
interpret(parses[0], arithmetic_augmentations)
```

[97]:
```
16
```

And we can even write a function that parses and interprets a string. We'll have it evaluate each of the possible parses and print the results.

[98]:
```
def parse_and_interpret(string, grammar, augmentations):
    parser = nltk.parse.BottomUpChartParser(grammar)
    parses = parser.parse(string.split())
    for parse in parses:
        parse.pretty_print()
        print(parse, "==>", interpret(parse, augmentations))
```

[99]:
```
parse_and_interpret("three plus one times four", arithmetic_grammar,␣
↪arithmetic_augmentations)
```

```
            S
         ____|_________
        S         |     |
    ____|____     |     |
   S    OP   S    OP    S
   |    |    |    |     |
  NUM  ADD  NUM  MULT  NUM
   |    |    |    |     |
three plus one times four

(S
  (S (S (NUM three)) (OP (ADD plus)) (S (NUM one)))
  (OP (MULT times))
  (S (NUM four))) ==> 16
            S
    ________|____
   |    |         S
   |    |     ____|____
   S    OP   S    OP    S
   |    |    |    |     |
  NUM  ADD  NUM  MULT  NUM
   |    |    |    |     |
three plus one times four

(S
  (S (NUM three))
  (OP (ADD plus))
  (S (S (NUM one)) (OP (MULT times)) (S (NUM four)))) ==> 7
```

Since the string is syntactically ambiguous according to the grammar, it is semantically ambiguous as well.

3.2 Some grammar specification conveniences

Before going on, it will be useful to have a few more conveniences in writing augmentations for rules. First, since the augmentations are arbitrary Python expressions, they can be built from and make use of other functions. For instance, you'll notice that many of the augmentations at the leaves of the tree took no arguments and returned a constant. We can define a function `constant`

that returns a function that ignores its arguments and returns a particular value.

[100]:
```
def constant(value):
    """Return `value`, ignoring any arguments"""
    return lambda *args: value
```

Similarly, several of the augmentations are functions that just return their first argument. Again, we can define a generic form `first` of such a function:

[101]:
```
def first(*args):
    """Return the value of the first (and perhaps only) subconstituent,
       ignoring any others"""
    return args[0]
```

We can now rewrite the grammar above to take advantage of these shortcuts.

> In the call to `parse_augmented_grammar` below, we pass in the global environment, extracted via a `globals()` function call, via the named argument `globals`. This allows the `parse_augmented_grammar` function to make use of the global bindings for `constant`, `first`, and the like when evaluating the augmentation expressions to their values. You can check out the code in `transform.py` to see how the passed in `globals` bindings are used. To help understand what's going on, see what happens if you don't include the `globals=globals()`.

[102]:
```
arithmetic_grammar_2, arithmetic_augmentations_2 = xform.
↪parse_augmented_grammar(
    """
    ## Sample grammar for arithmetic expressions

    S -> NUM                                : first
       | S OP S                             : lambda S1, Op, S2: Op(S1, S2)

    OP -> ADD                               : first
       | SUB
       | MULT
       | DIV

    NUM -> 'zero'                           : constant(0)
         | 'one'                            : constant(1)
         | 'two'                            : constant(2)
         | 'three'                          : constant(3)
         | 'four'                           : constant(4)
         | 'five'                           : constant(5)
         | 'six'                            : constant(6)
         | 'seven'                          : constant(7)
         | 'eight'                          : constant(8)
         | 'nine'                           : constant(9)
         | 'ten'                            : constant(10)
```

```
    ADD -> 'plus' | 'added' 'to'          : constant(lambda x, y: x + y)
    SUB -> 'minus'                        : constant(lambda x, y: x - y)
    MULT -> 'times' | 'multiplied' 'by'   : constant(lambda x, y: x * y)
    DIV -> 'divided' 'by'                 : constant(lambda x, y: x / y)
    """,
    globals=globals())
```

Finally, it might make our lives easier to write a template of augmentations whose instantiation depends on the right-hand side of the rule.

We use a reserved keyword `_RHS` to denote the right-hand side of the syntactic rule, which will be replaced by a **list** of the right-hand-side strings. For example, an augmentation `numeric_template(_RHS)` would be as if written as `numeric_template(['zero'])` when the rule is `NUM -> 'zero'`, and `numeric_template(['one'])` when the rule is `NUM -> 'one'`. The details of how this works can be found at scripts/transform.py.

This would allow us to use a single template function, for example,

[103]:
```
def numeric_template(rhs):
    """Ignore the subphrase meanings and lookup the first right-hand-side␣
 ↪symbol
       as a number"""
    return constant({'zero': 0, 'one': 1, 'two': 2, 'three': 3, 'four': 4,␣
 ↪'five': 5,
                     'six': 6, 'seven': 7, 'eight': 8, 'nine': 9, 'ten':␣
 ↪10}[rhs[0]])
```

and then further simplify the grammar specification:

[104]:
```
arithmetic_grammar_3, arithmetic_augmentations_3 = xform.
 ↪parse_augmented_grammar(
    """
    ## Sample grammar for arithmetic expressions

    S -> NUM                              : first
       | S OP S                           : lambda S1, Op, S2: Op(S1, S2)

    OP -> ADD                             : first
       | SUB
       | MULT
       | DIV

    NUM -> 'zero'  | 'one'   | 'two'      : numeric_template(_RHS)
         | 'three' | 'four'  | 'five'
         | 'six'   | 'seven' | 'eight'
         | 'nine'  | 'ten'
```

```
    ADD -> 'plus' | 'added' 'to'          : constant(lambda x, y: x + y)
    SUB -> 'minus'                        : constant(lambda x, y: x - y)
    MULT -> 'times' | 'multiplied' 'by'   : constant(lambda x, y: x * y)
    DIV -> 'divided' 'by'                 : constant(lambda x, y: x / y)
    """,
    globals=globals())
```

[105]:
```
parse_and_interpret("six divided by three", arithmetic_grammar_3,␣
↪arithmetic_augmentations_3)
```

```
       S

 |       _____|___     |
six divided      by three

(S (S (NUM six)) (OP (DIV divided by)) (S (NUM three))) ==> 2.0
```

3.3 Example: *Green Eggs and Ham* revisited

This stuff is tricky, so it's useful to see more examples before jumping in the deep end. In this simple GEaH fragment grammar, we use a larger set of auxiliary functions to build the augmentations.

[106]:
```
def forward(F, A):
    """Forward application: Return the application of the first
       argument to the second"""
    return F(A)

def backward(A, F):
    """Backward application: Return the application of the second
       argument to the first"""
    return F(A)

def second(*args):
    """Return the value of the second subconstituent, ignoring any others"""
    return args[1]

def ignore(*args):
    """Return `None`, ignoring everything about the constituent. (Good as a
       placeholder until a better augmentation can be devised.)"""
    return None
```

Using these, we can build and test the grammar.

[107]:
```
geah_grammar_spec = """
    ## Productions
    S -> NP VP              : backward
    VP -> V NP              : forward

    ## Lexicon
    V -> 'likes'            : constant(lambda Object: lambda Subject:␣
 ↪f"like({Subject}, {Object})")
    NP -> 'Sam' | 'sam'     : constant(_RHS[0])
    NP -> 'ham'
    NP -> 'eggs'
"""
```

[108]:
```
geah_grammar, geah_augmentations = xform.
 ↪parse_augmented_grammar(geah_grammar_spec,
                                                                  ␣
 ↪globals=globals())
```

[109]:
```
parse_and_interpret("Sam likes ham", geah_grammar, geah_augmentations)
```

```
      S
  ____|____
 |         VP
 |     ____|___
 NP   V        NP
 |    |        |
Sam likes     ham

(S (NP Sam) (VP (V likes) (NP ham))) ==> like(Sam, ham)
```

4 Semantics of ATIS queries

Now you're in a good position to understand and add augmentations to a more comprehensive grammar, say, one that parses ATIS queries and generates SQL queries.

In preparation for that, we need to load the ATIS data, both NL and SQL queries.

4.1 Loading and preprocessing the corpus

To simplify things a bit, we'll only consider ATIS queries whose question type (remember that from project segment 1?) is `flight_id`. We download training, development, and test splits for this subset of the ATIS corpus, including corresponding SQL queries.

[110]:
```
# Acquire the datasets - training, development, and test splits of the
# ATIS queries and corresponding SQL queries
download_if_needed(source_url, "data/", "/ATIS/test_flightid.nl")
download_if_needed(source_url, "data/", "/ATIS/test_flightid.sql")
download_if_needed(source_url, "data/", "/ATIS/dev_flightid.nl")
```

```
download_if_needed(source_url, "data/", "/ATIS/dev_flightid.sql")
download_if_needed(source_url, "data/", "/ATIS/train_flightid.nl")
download_if_needed(source_url, "data/", "/ATIS/train_flightid.sql")
```

[111]:
```
# Process data
for split in ['train', 'dev', 'test']:
    src_in_file = f'data/{split}_flightid.nl'
    tgt_in_file = f'data/{split}_flightid.sql'
    out_file = f'data/{split}.csv'

    with open(src_in_file, 'r') as f_src_in, open(tgt_in_file, 'r') as f_tgt_in:
        with open(out_file, 'w') as f_out:
            src, tgt= [], []
            writer = csv.writer(f_out)
            writer.writerow(('src','tgt'))
            for src_line, tgt_line in zip(f_src_in, f_tgt_in):
                writer.writerow((src_line.strip(), tgt_line.strip()))
```

Let's take a look at what the data file looks like.

[112]:
```
shell("head -2 data/dev.csv")
```

```
huggingface/tokenizers: The current process just got forked, after parallelism
has already been used. Disabling parallelism to avoid deadlocks…
To disable this warning, you can either:
        - Avoid using `tokenizers` before the fork if possible
        - Explicitly set the environment variable TOKENIZERS_PARALLELISM=(true |
false)
src,tgt
what flights are available tomorrow from denver to philadelphia,"SELECT DISTINCT
flight_1.flight_id FROM flight flight_1 , airport_service airport_service_1 ,
city city_1 , airport_service airport_service_2 , city city_2 , days days_1 ,
date_day date_day_1 WHERE flight_1.from_airport = airport_service_1.airport_code
AND airport_service_1.city_code = city_1.city_code AND city_1.city_name =
'DENVER' AND ( flight_1.to_airport = airport_service_2.airport_code AND
airport_service_2.city_code = city_2.city_code AND city_2.city_name =
'PHILADELPHIA' AND flight_1.flight_days = days_1.days_code AND days_1.day_name =
date_day_1.day_name AND date_day_1.year = 1991 AND date_day_1.month_number = 1
AND date_day_1.day_number = 20 )"
```

4.2 Corpus preprocessing

We'll use `tokenizers` and `datasets` to process the data. We'll use the NLTK tokenizer from project segment 3.

[113]:
```
# NLTK Tokenizer
tokenizer_pattern = '\d+|st\.|[\w-]+|\$[\d\.]+|\S+'
nltk_tokenizer = nltk.tokenize.RegexpTokenizer(tokenizer_pattern)
```

```
def tokenize_nltk(string):
    return nltk_tokenizer.tokenize(string.lower())

# Demonstrating the tokenizer
# Note especially the handling of `"11pm"` and hyphenated words.
print(tokenize_nltk(
    "Are there any first-class flights from St. Louis at 11pm for less than $3.
 ↪50?"))
```

```
['are', 'there', 'any', 'first-class', 'flights', 'from', 'st.', 'louis', 'at',
'11', 'pm', 'for', 'less', 'than', '$3.50', '?']
```

[114]:
```
dataset = load_dataset('csv', data_files={'train': f'data/train.csv',
                                          'val': f'data/dev.csv',
                                          'test': f'data/test.csv'})
dataset
```

```

        features: ['src', 'tgt'],
        num_rows: 332
    })
})
```

[115]:
```
train_data = dataset['train']
val_data = dataset['val']
test_data = dataset['test']
```

[116]:
```
MIN_FREQ = 3
unk_token = '[UNK]'
pad_token = '[PAD]'
bos_token = '<bos>'
eos_token = '<eos>'

src_tokenizer = Tokenizer(WordLevel(unk_token=unk_token))
src_tokenizer.normalizer = normalizers.Lowercase()
src_tokenizer.pre_tokenizer = Split(Regex(tokenizer_pattern),␣
 ↪behavior='removed', invert=True)

src_trainer = WordLevelTrainer(min_frequency=MIN_FREQ,␣
 ↪special_tokens=[pad_token, unk_token])
src_tokenizer.train_from_iterator(train_data['src'], trainer=src_trainer)

tgt_tokenizer = Tokenizer(WordLevel(unk_token=unk_token))
tgt_tokenizer.pre_tokenizer = WhitespaceSplit()
```

```
tgt_trainer = WordLevelTrainer(min_frequency=MIN_FREQ,␣
 ↪special_tokens=[pad_token, unk_token, bos_token, eos_token])

tgt_tokenizer.train_from_iterator(train_data['tgt'], trainer=tgt_trainer)

tgt_tokenizer.post_processor = TemplateProcessing(single=f"{bos_token} $A␣
 ↪{eos_token}", special_tokens=[(bos_token, tgt_tokenizer.
 ↪token_to_id(bos_token)), (eos_token, tgt_tokenizer.token_to_id(eos_token))])
```

Note that we prepended `<bos>` and appended `<eos>` to target sentences.

We use `datasets.Dataset.map` to convert text into word ids. As shown in lab 1-5, first we need to wrap `tokenizer` with the `transformers.PreTrainedTokenizerFast` class to be compatible with the `datasets` library.

[117]:
```
hf_src_tokenizer = PreTrainedTokenizerFast(tokenizer_object=src_tokenizer,␣
 ↪pad_token=pad_token)
hf_tgt_tokenizer = PreTrainedTokenizerFast(tokenizer_object=tgt_tokenizer,␣
 ↪pad_token=pad_token, bos_token=bos_token, eos_token=eos_token)

def encode(example):
    example['src_ids'] = hf_src_tokenizer(example['src']).input_ids
    example['tgt_ids'] = hf_tgt_tokenizer(example['tgt']).input_ids
    return example

train_data = train_data.map(encode)
val_data = val_data.map(encode)
test_data = test_data.map(encode)
```

```
  0%|          | 0/3651 [00:00<?, ?ex/s]
  0%|          | 0/398 [00:00<?, ?ex/s]
  0%|          | 0/332 [00:00<?, ?ex/s]
```

[118]:
```
# Compute size of vocabulary
src_vocab = src_tokenizer.get_vocab()
tgt_vocab = tgt_tokenizer.get_vocab()

print(f"Size of English vocab: {len(src_vocab)}")
print(f"Size of SQL vocab: {len(tgt_vocab)}")
print(f"Index for src padding: {src_vocab[pad_token]}")
print(f"Index for tgt padding: {tgt_vocab[pad_token]}")
print(f"Index for start of sequence token: {tgt_vocab[bos_token]}")
print(f"Index for end of sequence token: {tgt_vocab[eos_token]}")
```

```
Size of English vocab: 421
Size of SQL vocab: 392
```

```
Index for src padding: 0
Index for tgt padding: 0
Index for start of sequence token: 2
Index for end of sequence token: 3
```

Next, we batch our data to facilitate processing on a GPU. Batching is a bit tricky because the source and target will typically be of different lengths and have to padd the sequences to the same length. Since there is padding, we need to handle them with `pack` and `unpack` later on in the seq2seq part (as in lab 4-5).

[119]:
```
BATCH_SIZE = 16     # batch size for training and validation
TEST_BATCH_SIZE = 1 # batch size for test; we use 1 to make implementation␣
 ↪easier

# Defines how to batch a list of examples together
def collate_fn(examples):
    batch = {}
    bsz = len(examples)
    src_ids, tgt_ids = [], []
    for example in examples:
        src_ids.append(example['src_ids'])
        tgt_ids.append(example['tgt_ids'])

    src_len = torch.LongTensor([len(word_ids) for word_ids in src_ids]).
 ↪to(device)
    src_max_length = max(src_len)
    tgt_max_length = max([len(word_ids) for word_ids in tgt_ids])

    src_batch = torch.zeros(bsz, src_max_length).long().
 ↪fill_(src_vocab[pad_token]).to(device)
    tgt_batch = torch.zeros(bsz, tgt_max_length).long().
 ↪fill_(tgt_vocab[pad_token]).to(device)
    for b in range(bsz):
        src_batch[b][:len(src_ids[b])] = torch.LongTensor(src_ids[b]).to(device)
        tgt_batch[b][:len(tgt_ids[b])] = torch.LongTensor(tgt_ids[b]).to(device)

    batch['src_lengths'] = src_len
    batch['src_ids'] = src_batch
    batch['tgt_ids'] = tgt_batch
    return batch

train_iter = torch.utils.data.DataLoader(train_data,
                                         batch_size=BATCH_SIZE,
                                         shuffle=True,
                                         collate_fn=collate_fn)
val_iter = torch.utils.data.DataLoader(val_data,
                                       batch_size=BATCH_SIZE,
                                       shuffle=False,
```

```
                                             collate_fn=collate_fn)
test_iter = torch.utils.data.DataLoader(test_data,
                                        batch_size=TEST_BATCH_SIZE,
                                        shuffle=False,
                                        collate_fn=collate_fn)
```

Let's look at a single batch from one of these iterators.

[120]:
```
batch = next(iter(train_iter))
src_ids = batch['src_ids']
src_example = src_ids[2]
print (f"Size of text batch: {src_ids.size()}")
print (f"Third sentence in batch: {src_example}")
print (f"Length of the third sentence in batch: {len(src_example)}")
print (f"Converted back to string: {hf_src_tokenizer.decode(src_example)}")

tgt_ids = batch['tgt_ids']
tgt_example = tgt_ids[2]
print (f"Size of sql batch: {tgt_ids.size()}")
print (f"Third sql in batch: {tgt_example}")
print (f"Converted back to string: {hf_tgt_tokenizer.decode(tgt_example)}")
```

```
Size of text batch: torch.Size([16, 30])
Third sentence in batch: torch.Size([30])
Length of the third sentence in batch: 30
Converted back to string: show me flights from san francisco to boston on
thursday [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
Size of sql batch: torch.Size([16, 153])
Third sql in batch: torch.Size([153])
Converted back to string: <bos> SELECT DISTINCT flight_1.flight_id FROM flight
flight_1, airport_service airport_service_1, city city_1, airport_service
airport_service_2, city city_2, days days_1, date_day date_day_1 WHERE
flight_1.from_airport = airport_service_1.airport_code AND
airport_service_1.city_code = city_1.city_code AND city_1.city_name = 'SAN
FRANCISCO' AND ( flight_1.to_airport = airport_service_2.airport_code AND
airport_service_2.city_code = city_2.city_code AND city_2.city_name = 'BOSTON'
AND flight_1.flight_days = days_1.days_code AND days_1.day_name =
date_day_1.day_name AND date_day_1.year = 1991 AND date_day_1.month_number = 5
AND date_day_1.day_number = 24 ) <eos> [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
[PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD] [PAD]
```

Alternatively, we can directly iterate over the raw examples:

[121]:
```
for _, example in zip(range(1), train_data):
    train_text_1 = example['src']  # detokenized question
    train_sql_1 = example['tgt']  # detokenized sql
    print(f"Question: {train_text_1}\n")
    print(f"SQL: {train_sql_1}")
```

```
Question: list all the flights that arrive at general mitchell international
from various cities

SQL: SELECT DISTINCT flight_1.flight_id FROM flight flight_1 , airport airport_1
, airport_service airport_service_1 , city city_1 WHERE flight_1.to_airport =
airport_1.airport_code AND airport_1.airport_code = 'MKE' AND
flight_1.from_airport = airport_service_1.airport_code AND
airport_service_1.city_code = city_1.city_code AND 1 = 1
```

4.3 Establishing an SQL database for evaluating ATIS queries

The output of our systems will be SQL queries. How should we determine if the generated queries are correct? We can't merely compare against the gold SQL queries, since there are many ways to implement a SQL query that answers any given NL query.

Instead, we will execute the queries – both the predicted SQL query and the gold SQL query – on an actual database, and verify that the returned responses are the same. For that purpose, we need an SQL database server to use. We'll set one up here, using the Python `sqlite3` module.

[122]:
```
@func_set_timeout(TIMEOUT)
def execute_sql(sql):
    # establish the DB based on the downloaded data
    conn = sqlite3.connect('data/atis_sqlite.db')
    c = conn.cursor()                                # build a "cursor"
    c.execute(sql)
    results = list(c.fetchall())
    c.close()
    conn.close()
    return results
```

To run a query, we use the cursor's `execute` function, and retrieve the results with `fetchall`. Let's get all the flights that arrive at General Mitchell International – the query `train_sql_1` above. There's a lot, so we'll just print out the first few.

[123]:
```
predicted_ret = execute_sql(train_sql_1)

print(f"""
Executing: {train_sql_1}

Result: {len(predicted_ret)} entries starting with

{predicted_ret[:10]}
```

```
""")
```

```
Executing: SELECT DISTINCT flight_1.flight_id FROM flight flight_1 , airport
airport_1 , airport_service airport_service_1 , city city_1 WHERE
flight_1.to_airport = airport_1.airport_code AND airport_1.airport_code = 'MKE'
AND flight_1.from_airport = airport_service_1.airport_code AND
airport_service_1.city_code = city_1.city_code AND 1 = 1

Result: 534 entries starting with

[(107929,), (107930,), (107931,), (107932,), (107933,), (107934,), (107935,),
(107936,), (107937,), (107938,)]
```

For your reference, the SQL database we are using has a database schema described at https://github.com/jkkummerfeld/text2sql-data/blob/master/data/atis-schema.csv, and is consistent with the SQL queries provided in the various `.sql` files loaded above.

5 Rule-based parsing and interpretation of ATIS queries

First, you will implement a rule-based semantic parser using a grammar like the one you completed in the third project segment. We've placed an initial grammar in the file `data/grammar`. In addition to the helper functions defined above (`constant`, `first`, etc.), it makes use of some other simple functions. We've included those below, but you can (and almost certainly should) augment this set with others that you define as you build out the full set of augmentations.

[124]:
```
def upper(term):
    return '"' + term.upper() + '"'

def weekday(day):
    return f"flight.flight_days IN (SELECT days.days_code FROM days WHERE days.
 ↪day_name = '{day.upper()}')"

def month_name(month):
    return {'JANUARY': 1,
            'FEBRUARY': 2,
            'MARCH': 3,
            'APRIL': 4,
            'MAY': 5,
            'JUNE': 6,
            'JULY': 7,
            'AUGUST': 8,
            'SEPTEMBER': 9,
            'OCTOBER': 10,
```

```
            'NOVEMBER': 11,
            'DECEMBER': 12}[month.upper()]

def airports_from_airport_name(airport_name):
    return f"(SELECT airport.airport_code FROM airport WHERE airport.
 ↪airport_name = {upper(airport_name)})"

def airports_from_city(city):
    return f"""
    (SELECT airport_service.airport_code FROM airport_service WHERE␣
 ↪airport_service.city_code IN
      (SELECT city.city_code FROM city WHERE city.city_name = {upper(city)}))
  """

def null_condition(*args, **kwargs):
    return 1

def depart_around(time):
    return f"""
    flight.departure_time >= {add_delta(miltime(time), -15).strftime('%H%M')}
    AND flight.departure_time <= {add_delta(miltime(time), 15).strftime('%H%M')}
    """.strip()

def add_delta(tme, delta):
    # transform to a full datetime first
    return (datetime.datetime.combine(datetime.date.today(), tme) +
            datetime.timedelta(minutes=delta)).time()

def miltime(minutes):
    return datetime.time(hour=int(minutes/100), minute=(minutes % 100))
```

[125]:
```
def from_place(_from, place):
    return f"flight.from_airport IN {place}"

def to_place(to, place):
    return f"flight.to_airport IN {place}"

def via_place(place):
    return None
```

```
def between_places(place1, place2):
    return f"flight.from_airport IN {place1} AND flight.to_airport IN {place2}"

def airline_code(code):
    return f"flight.airline_code = '{code}'"

def cond_and_cond(cond1, cond2):
    return f"{cond1} AND {cond2}"

def distinct(cond):
    return f"SELECT DISTINCT flight.flight_id FROM flight WHERE {cond}"
```

We can build a parser with the augmented grammar:

[126]:
```
atis_grammar, atis_augmentations = xform.read_augmented_grammar('data/grammar',␣
 ↪globals=globals())
atis_parser = nltk.parse.BottomUpChartParser(atis_grammar)
```

We'll define a function to return a parse tree for a string according to the ATIS grammar (if available).

[127]:
```
def parse_tree(sentence):
    """Parse a sentence and return the parse tree, or None if failure."""
    try:
        parses = list(atis_parser.parse(tokenize_nltk(sentence)))
        if len(parses) == 0:
            return None
        else:
            return parses[0]
    except:
        return None
```

We can check the overall coverage of this grammar on the training set by using the `parse_tree` function to determine if a parse is available. The grammar that we provide should get about a 44% coverage of the training set.

[128]:
```
# Check coverage on training set
parsed = 0
with open("data/train_flightid.nl") as train:
    examples = train.readlines()[:]
for sentence in tqdm(examples):
    if parse_tree(sentence):
        parsed += 1
    else:
```

```
        next

print(
    f"\nParsed {parsed} of {len(examples)} ({parsed*100/(len(examples)):.2f}%)")
```

```
100%|      | 3651/3651 [00:33<00:00, 109.42it/s]

Parsed 1609 of 3651 (44.07%)
```

5.1 Goal 1: Construct SQL queries from a parse tree and evaluate the results

It's time to turn to the first major part of this project segment, implementing a rule-based semantic parsing system to answer flight-ID-type ATIS queries.

Recall that in rule-based semantic parsing, each syntactic rule is associated with a semantic composition rule. The grammar we've provided has semantic augmentations for some of the low-level phrases – cities, airports, times, airlines – but not the higher level syntactic types. You'll be adding those.

In the ATIS grammar that we provide, as with the earlier toy grammars, the augmentation for a rule with n nonterminals and m terminals on the right-hand side is assumed to be called with n positional arguments (the values for the corresponding children). The `interpret` function you've already defined should therefore work well with this grammar.

Let's run through one way that a semantic derivation might proceed, for the sample query "flights to boston":

[129]:
```
sample_query = "flights to boston"
print(tokenize_nltk(sample_query))
sample_tree = parse_tree(sample_query)
sample_tree.pretty_print()
```

```
['flights', 'to', 'boston']
                S
                |
                SD
                |
            NP_FLIGHT
                |
            NOM_FLIGHT
                |
             N_FLIGHT
          ----------|---------
     |                    PP
     |                    |
     |                PP_PLACE
     |           ---------|---------
  N_FLIGHT       |               N_PLACE
```

```
     |          |                  |
TERM_FLIGHT P_PLACE_TO          TERM_PLACE
     |          |                  |
  flights       to                boston
```

Given a sentence, we first construct its parse tree using the syntactic rules, then compose the corresponding semantic rules bottom-up, until eventually we arrive at the root node with a finished SQL statement. For this query, we will go through what the possible meaning representations for the subconstituents of "flights to boston" might be. But this is just one way of doing things; other ways are possible, and you should feel free to experiment.

Working from bottom up:

1. The `TERM_PLACE` phrase "boston" uses the composition function template `constant(airports_from_city(' '.join(_RHS)))`, which will be instantiated as `constant(airports_from_city(' '.join(['boston'])))` (recall that `_RHS` is replaced by the right-hand side of the rule). The meaning of `TERM_PLACE` will be the SQL snippet

```
SELECT airport_service.airport_code
FROM airport_service
WHERE airport_service.city_code IN
    (SELECT city.city_code
     FROM city
     WHERE city.city_name = "BOSTON")
```

(This query generates a list of all of the airports in Boston.)

2. The `N_PLACE` phrase "boston" can have the same meaning as the `TERM_PLACE`.
3. The `P_PLACE` phrase "to" might be associated with a function that maps a SQL query for a list of airports to a SQL condition that holds of flights that go to one of those airports, i.e., `flight.to_airport IN (...)`.
4. The `PP_PLACE` phrase "to boston" might apply the `P_PLACE` meaning to the `TERM_PLACE` meaning, thus generating a SQL condition that holds of flights that go to one of the Boston airports:

```
flight.to_airport IN
    (SELECT airport_service.airport_code
     FROM airport_service
     WHERE airport_service.city_code IN
         (SELECT city.city_code
          FROM city
          WHERE city.city_name = "BOSTON"))
```

5. The `PP` phrase "to Boston" can again get its meaning from the `PP_PLACE`.
6. The `TERM_FLIGHT` phrase "flights" might also return a condition on flights, this time the "null condition", represented by the SQL truth value `1`. Ditto for the `N_FLIGHT` phrase "flights".
7. The `N_FLIGHT` phrase "flights to boston" can conjoin the two conditions, yielding the SQL condition

```
flight.to_airport IN
    (SELECT airport_service.airport_code
     FROM airport_service
     WHERE airport_service.city_code IN
         (SELECT city.city_code
          FROM city
          WHERE city.city_name = "BOSTON"))
AND 1
```

which can be inherited by the NOM_FLIGHT and NP_FLIGHT phrases.

8. The S phrase "flights to boston" can use the condition provided by the NP_FLIGHT phrase to select all flights satisfying the condition with a SQL query like

```
SELECT DISTINCT flight.flight_id
FROM flight
WHERE flight.to_airport IN
        (SELECT airport_service.airport_code
         FROM airport_service
         WHERE airport_service.city_code IN
             (SELECT city.city_code
              FROM city
              WHERE city.city_name = "BOSTON"))
      AND 1
```

This SQL query is then taken to be a representation of the meaning for the NL query "flights to boston", and can be executed against the ATIS database to retrieve the requested flights.

Now, it's your turn to add augmentations to `data/grammar` to make this example work. The augmentations that we have provided for the grammar make use of a set of auxiliary functions that we defined above. You should feel free to add your own auxiliary functions that you make use of in the grammar.

[130]:
```
#TODO: add augmentations to `data/grammar` to make this example work
atis_grammar, atis_augmentations = xform.read_augmented_grammar('data/grammar',␣
 ↪globals=globals())
atis_parser = nltk.parse.BottomUpChartParser(atis_grammar)
predicted_sql = interpret(sample_tree, atis_augmentations)
print("Predicted SQL:\n\n", predicted_sql, "\n")
```

```
Predicted SQL:

 SELECT DISTINCT flight.flight_id FROM flight WHERE 1 AND flight.to_airport IN
    (SELECT airport_service.airport_code FROM airport_service WHERE
airport_service.city_code IN
      (SELECT city.city_code FROM city WHERE city.city_name = "BOSTON"))
```

Verification on some examples With a rule-based semantic parsing system, we can generate SQL queries given questions, and then execute those queries on a SQL database to answer the given questions. To evaluate the performance of the system, we compare the returned results against the results of executing the ground truth queries.

We provide a function `verify` to compare the results from our generated SQL to the ground truth SQL. It should be useful for testing individual queries.

[131]:
```
def verify(predicted_sql, gold_sql, silent=True):
    """
    Compare the correctness of the generated SQL by executing on the
    ATIS database and comparing the returned results.
    Arguments:
        predicted_sql: the predicted SQL query
        gold_sql: the reference SQL query to compare against
        silent: print outputs or not
    Returns: True if the returned results are the same, otherwise False
    """
    # Execute predicted SQL
    try:
        predicted_result = execute_sql(predicted_sql)
    except BaseException as e:
        if not silent:
            print(f"predicted sql exec failed: {e}")
        return False
    if not silent:
        print("Predicted DB result:\n\n", predicted_result[:10], "\n")

    # Execute gold SQL
    try:
        gold_result = execute_sql(gold_sql)
    except BaseException as e:
        if not silent:
            print(f"gold sql exec failed: {e}")
        return False
    if not silent:
        print("Gold DB result:\n\n", gold_result[:10], "\n")

    # Verify correctness
    if gold_result == predicted_result:
        return True
```

Let's try this methodology on a simple example: "flights from phoenix to milwaukee". we provide it along with the gold SQL query.

[132]:
```
def rule_based_trial(sentence, gold_sql):
    print("Sentence: ", sentence, "\n")
    tree = parse_tree(sentence)
```

```
    print("Parse:\n\n")
    tree.pretty_print()

    predicted_sql = interpret(tree, atis_augmentations)
    print("Predicted SQL:\n\n", predicted_sql, "\n")

    if verify(predicted_sql, gold_sql, silent=False):
        print('Correct!')
    else:
        print('Incorrect!')
```

[133]:
```
# Run this cell to reload augmentations after you make changes to `data/grammar`
atis_grammar, atis_augmentations = xform.read_augmented_grammar('data/grammar',␣
 ↪globals=globals())
atis_parser = nltk.parse.BottomUpChartParser(atis_grammar)
```

[134]:
```
# TODO: add augmentations to `data/grammar` to make this example work
# Example 1
example_1 = 'flights from phoenix to milwaukee'
gold_sql_1 = """
    SELECT DISTINCT flight_1.flight_id
    FROM flight flight_1 ,
       airport_service airport_service_1 ,
       city city_1 ,
       airport_service airport_service_2 ,
       city city_2
    WHERE flight_1.from_airport = airport_service_1.airport_code
        AND airport_service_1.city_code = city_1.city_code
        AND city_1.city_name = 'PHOENIX'
        AND flight_1.to_airport = airport_service_2.airport_code
        AND airport_service_2.city_code = city_2.city_code
        AND city_2.city_name = 'MILWAUKEE'
    """

rule_based_trial(example_1, gold_sql_1)
```

```
Sentence:  flights from phoenix to milwaukee

Parse:

                S

5.1.1 Systematic evaluation on a test set

We can perform a more systematic evaluation by checking the accuracy of the queries on an entire test set for which we have gold queries. The `evaluate` function below does just this, calculating precision, recall, and F1 metrics for the test set. It takes as argument a "predictor" function, which maps token sequences to predicted SQL queries. We've provided a predictor function for the rule-based model in the next cell (and a predictor for the seq2seq system below when we get to that system).

The rule-based system does not generate predictions for all queries; many queries won't parse. The precision and recall metrics take this into account in measuring the efficacy of the method. The recall metric captures what proportion of *all of the test examples* for which the system generates a correct query. The precision metric captures what proportion of *all of the test examples for which a prediction is generated* for which the system generates a correct query. (Recall that F1 is just the geometric mean of precision and recall.)

Once you've made some progress on adding augmentations to the grammar, you can evaluate your progress by seeing if the precision and recall have improved. For reference, the solution code achieves precision of about 66% and recall of about 28% for an F1 of 39%.

[142]:
```
def evaluate(predictor, dataset, num_examples=0, silent=True):
    """Evaluate accuracy of `predictor` by executing predictions on a
    SQL database and comparing returned results against those of gold queries.

    Arguments:
        predictor:    a function that maps a token sequence
                      to a predicted SQL query string
        dataset:      the dataset of token sequences and gold SQL queries
        num_examples: number of examples from `dataset` to use; all of
                      them if 0
        silent: if set to False, will print out logs
    Returns: precision, recall, and F1 score

6 End-to-End Seq2Seq Model

In this part, you will implement a seq2seq model **with attention mechanism** to directly learn the translation from NL query to SQL. You might find labs 4-4 and 4-5 particularly helpful, as the primary difference here is that we are using a different dataset.

Note: We recommend using GPUs to train the model in this part (one way to get GPUs is to use Google Colab and clicking Menu -> Runtime -> Change runtime type -> GPU), as we need to use a very large model to solve the task well. For development we recommend starting with a smaller model and training for only 1 epoch.

6.1 Goal 2: Implement a seq2seq model (with attention)

In lab 4-5, you implemented a neural encoder-decoder model with attention. That model was used to convert English number phrases to numbers, but one of the biggest advantages of neural models is that we can easily apply them to different tasks (such as machine translation and document summarization) by using different training datasets.

Implement the class `AttnEncoderDecoder` to convert natural language queries into SQL statements. You may find that you can reuse most of the code you wrote for lab 4-5. A reasonable way to proceed is to implement the following methods:

- **Model**
  1. `__init__`: an initializer where you create network modules.
  2. `forward`: given source word ids of size `(batch_size, max_src_len)`, source lengths of size `(batch_size)` and decoder input target word ids `(batch_size, max_tgt_len)`, returns logits `(batch_size, max_tgt_len, V_tgt)`. For better modularity you might want to implement it by implementing two functions `forward_encoder` and `forward_decoder`.
- **Optimization**
  3. `train_all`: compute loss on training data, compute gradients, and update model parameters to minimize the loss.
  4. `evaluate_ppl`: evaluate the current model's perplexity on a given dataset iterator, we use the perplexity value on the validation set to select the best model.
- **Decoding**
  5. `predict`: Generates the target sequence given a list of source tokens using beam search decoding. Note that here you can assume the batch size to be 1 for simplicity.

[145]:

6.1.1 Evaluation

Now we are ready to run the full evaluation. A proper implementation should reach more than 35% precision/recall/F1.

[159]:
```
def seq2seq_predictor(tokens):
  prediction = model.predict(tokens, K=1, max_T=400)
  return prediction
```

[160]:
```
precision, recall, f1 = evaluate(seq2seq_predictor, test_data, num_examples=0)
print(f"precision: {precision:3.2f}")
print(f"recall:    {recall:3.2f}")
print(f"F1:        {f1:3.2f}")
```

```
332it [01:54,  2.91it/s]

precision: 0.39
```

```
recall:    0.39
F1:        0.39
```

6.2 Goal 3: Implement a seq2seq model (with cross attention and self attention)

In the previous section, you have implemented a seq2seq model with attention. The attention mechanism used in that section is usually referred to as "cross-attention", as at each decoding step, the decoder attends to encoder outputs, enabling a dynamic view on the encoder side as decoding proceeds.

Similarly, we can have a dynamic view on the decoder side as well as decoding proceeds, i.e., the decoder attends to decoder outputs at previous steps. This is called "self attention", and has been found very useful in modern neural architectures such as transformers.

Augment the seq2seq model you implemented before with a decoder self-attention mechanism as class `AttnEncoderDecoder2`. A model diagram can be found below:

At each decoding step, the decoder LSTM first produces an output state o_t, then it attends to all previous output states $o_1, \ldots, o_{t-1}$ (decoder self-attention). You need to special case the first decoding step to not perform self-attention, as there are no previous decoder states. The attention result is added to o_t itself and the sum is used as q_t to attend to the encoder side (encoder-decoder cross-attention). The rest of the model is the same as encoder-decoder with attention.

[171]:
```python
# TODO - implement the `AttnEncoderDecoder2` class.
class AttnEncoderDecoder2(nn.Module):
    def __init__(self, hf_src_tokenizer, hf_tgt_tokenizer, hidden_size=64,␣
 ↪layers=3):
        """
        Initializer. Creates network modules and loss function.
        Arguments:
            hf_src_tokenizer: hf src tokenizer
            hf_tgt_tokenizer: hf tgt tokenizer
            hidden_size: hidden layer size of both encoder and decoder
            layers: number of layers of both encoder and decoder
        """
        super().__init__()
        self.hf_src_tokenizer = hf_src_tokenizer
        self.hf_tgt_tokenizer = hf_tgt_tokenizer

        # Keep the vocabulary sizes available

```
  def forward_decoder_incrementally(self, prev_decoder_hiddens,␣
↪tgt_in_onestep,
                                    memory_bank, src_mask,
                                    normalize=True,␣
↪prev_decoder_outputs=None):
      """
      Forward the decoder for a single step with token `tgt_in_onestep`.
      This function will be used both in `forward_decoder` and in beam search.
      Note that bsz can be greater than 1.
      Arguments:
          prev_decoder_hiddens: a tuple (prev_decoder_states, prev_context).␣
↪`prev_context`
                                is `None` for the first step
          tgt_in_onestep: a tensor of size (bsz), tokens at one step
          memory_bank: a tensor of size (bsz, src_len, hidden_size), encoder␣
↪outputs
                       at every position
          src_mask: a tensor of size (bsz, src_len): a boolean tensor,␣
↪`False` where
                    src is padding (we disallow decoder to attend to those␣
↪places).
          normalize: use log_softmax to normalize or not. Beam search needs␣
↪to normalize,
                     while `forward_decoder` does not
          prev_decoder_outputs: None or a tensor of size (bsc, layers,␣
↪timestep - 1, hidden_size)
      Returns:
          logits: log probabilities for `tgt_in_token` of size (bsz, V_tgt)
          decoder_states: (`decoder_state`, `context`) which will be used for␣
↪the
                          next incremental update
          attn: normalized attention scores at this step (bsz, src_len)
      """

6.2.1 Evaluation

Now we are ready to run the full evaluation. A proper implementation should reach more than 35% precision/recall/F1.

[164]:
```python
def seq2seq_predictor2(tokens):
  prediction = model2.predict(tokens, K=1, max_T=400)
  return prediction
```

[165]:
```python
precision, recall, f1 = evaluate(seq2seq_predictor2, test_data, num_examples=0)
print(f"precision: {precision:3.2f}")
print(f"recall:    {recall:3.2f}")
```

```
print(f"F1:        {f1:3.2f}")
```

```
332it [01:27,  3.81it/s]
```

```
precision: 0.39
recall:    0.39
F1:        0.39
```

6.3 Goal 4: Use state-of-the-art pretrained transformers

The most recent breakthrough in natural-language processing stems from the use of pretrained transformer models. For example, you might have heard of pretrained transformers such as GPT-3 and BERT. (BERT is already used in Google search.) These models are usually trained on vast amounts of text data using variants of language modeling objectives, and researchers have found that finetuning them on downstream tasks usually results in better performance as compared to training a model from scratch.

In the previous part, you implemented an LSTM-based sequence-to-sequence approach. To "upgrade" the model to be a state-of-the-art pretrained transformer only requires minor modifications.

The pretrained model that we will use is BART, which uses a bidirectional transformer encoder and a unidirectional transformer decoder, as illustrated in the below diagram (image courtesy https://arxiv.org/pdf/1910.13461):

We can see that this model is strikingly similar to the LSTM-based encoder-decoder model we've been using. The only difference is that they use transformers instead of LSTMs. Therefore, we only need to change the modeling parts of the code, as we will see later.

First, we download and load the pretrained BART model from the transformers package by Huggingface. Note that we also need to use the "tokenizer" of BART, which is actually a combination of a tokenizer and a mapping from strings to word ids.

[166]:
```
pretrained_bart = BartForConditionalGeneration.from_pretrained('facebook/
↪bart-base')
bart_tokenizer = BartTokenizer.from_pretrained('facebook/bart-base')
```

We need to reprocess the data using our new tokenizer. Note that we use the same tokenizer for both the source and target.

[167]:
```
def bart_encode(example):
    example['src_ids'] = [bart_tokenizer.bos_token_id] +␣
↪bart_tokenizer(example["src"]).input_ids[:1023] # BART model can process at␣
↪most 1024 tokens
    example['tgt_ids'] = [bart_tokenizer.bos_token_id] +␣
↪bart_tokenizer(example["tgt"]).input_ids[:1023]
    return example

train_bart_data = dataset['train'].map(bart_encode)
val_bart_data = dataset['val'].map(bart_encode)
```

```
test_bart_data = dataset['test'].map(bart_encode)

BATCH_SIZE = 1 # batch size for training/validation
TEST_BATCH_SIZE = 1 # batch size for test, we use 1 to make beam search␣
 ↪implementation easier

# we use the same collate function as before
train_iter_bart = torch.utils.data.DataLoader(train_bart_data,
                                              batch_size=BATCH_SIZE,
                                              shuffle=True,
                                              collate_fn=collate_fn)
val_iter_bart = torch.utils.data.DataLoader(val_bart_data,
                                            batch_size=BATCH_SIZE,
                                            shuffle=False,
                                            collate_fn=collate_fn)
test_iter_bart = torch.utils.data.DataLoader(test_bart_data,
                                             batch_size=TEST_BATCH_SIZE,
                                             shuffle=False,
                                             collate_fn=collate_fn)
```

```
  0%|          | 0/3651 [00:00<?, ?ex/s]
```

```
Token indices sequence length is longer than the specified maximum sequence
length for this model (1135 > 1024). Running this sequence through the model
will result in indexing errors
```

```
  0%|          | 0/398 [00:00<?, ?ex/s]
```

```
  0%|          | 0/332 [00:00<?, ?ex/s]
```

Let's take a look at the batch.

[179]:
```
batch = next(iter(train_iter_bart))
src_ids = batch['src_ids']
src_example = src_ids[0]
print (f"Size of text batch: {src_ids.size()}")
print (f"First sentence in batch: {src_example}")
print (f"Length of the third sentence in batch: {len(src_example)}")
print (f"Converted back to string: {bart_tokenizer.decode(src_example)}")

tgt_ids = batch['tgt_ids']
tgt_example = tgt_ids[0]
print (f"Size of sql batch: {tgt_ids.size()}")
print (f"First sql in batch: {tgt_example}")
print (f"Converted back to string: {bart_tokenizer.decode(tgt_example)}")
```

```
Size of text batch: torch.Size([1, 23])
First sentence in batch: torch.Size([23])
Length of the third sentence in batch: 23
Converted back to string: <s>please give me information on a flight on april
```

```
seventeen from philadelphia to boston as early as possible</s>
Size of sql batch: torch.Size([1, 488])
First sql in batch: torch.Size([488])
Converted back to string: <s>SELECT DISTINCT flight_1.flight_id FROM flight
flight_1, airport_service airport_service_1, city city_1, airport_service
airport_service_2, city city_2, days days_1, date_day date_day_1 WHERE
flight_1.departure_time = ( SELECT MIN ( flight_1.departure_time ) FROM flight
flight_1, airport_service airport_service_1, city city_1, airport_service
airport_service_2, city city_2, days days_1, date_day date_day_1 WHERE
flight_1.from_airport = airport_service_1.airport_code AND
airport_service_1.city_code = city_1.city_code AND city_1.city_name =
'PHILADELPHIA' AND ( flight_1.to_airport = airport_service_2.airport_code AND
airport_service_2.city_code = city_2.city_code AND city_2.city_name = 'BOSTON'
AND flight_1.flight_days = days_1.days_code AND days_1.day_name =
date_day_1.day_name AND date_day_1.year = 1991 AND date_day_1.month_number = 4
AND date_day_1.day_number = 17 ) ) AND ( flight_1.from_airport =
airport_service_1.airport_code AND airport_service_1.city_code =

1991 AND date_day_1.month_number = 4 AND date_day_1.day_number = 17 ) )</s>
```

Now we are ready to implement the BART-based approach for the text-to-SQL conversion problem. In the below `BART` class, we have provided the constructer `__init__`, the `forward` function, and the `predict` function. Your job is to implement the main optimization `train_all`, and `evaluate_ppl` for evaluating validation perplexity for model selection.

[196]:
```python
# TODO - finish implementing the `BART` class.
class BART(nn.Module):
    def __init__(self, tokenizer, pretrained_bart):
        """
        Initializer. Creates network modules and loss function.
        Arguments:
            tokenizer: BART tokenizer
            pretrained_bart: pretrained BART
        """
        super(BART, self).__init__()

        self.tokenizer = tokenizer

        self.V_tgt = len(tokenizer)

        # Get special word ids
        self.padding_id_tgt = tokenizer.pad_token_id

        # Create essential modules
        self.bart = pretrained_bart
```

```
        # Create loss function
        self.loss_function = nn.CrossEntropyLoss(reduction="sum",
                                                 ignore_index=self.
↪padding_id_tgt)

    def forward(self, src, src_lengths, tgt_in):
        """
        Performs forward computation, returns logits.
        Arguments:
            src: src batch of size (batch_size, max_src_len)
            src_lengths: src lengths of size (batch_size)
            tgt_in:  a tensor of size (batch_size, tgt_len)
        """
        # BART assumes inputs to be batch-first
        # This single function is forwarding both encoder and decoder (w/ cross␣
↪attn),
        # using `input_ids` as encoder inputs, and `decoder_input_ids`
        # as decoder inputs.
        logits = self.bart(input_ids=src,
                           decoder_input_ids=tgt_in,
                           use_cache=False
                           ).logits
        return logits

    def evaluate_ppl(self, iterator):
        """Returns the model's perplexity on a given dataset `iterator`."""

Correct!
```

6.3.1 Evaluation

The code below will evaluate on the entire test set. You should expect to see precision/recall/F1 greater than 40%.

[221]:
```
def seq2seq_predictor_bart(tokens):
  prediction = bart_model.predict(tokens, K=4, max_T=400)
  return prediction
```

[222]:
```
precision, recall, f1 = evaluate(seq2seq_predictor_bart, test_bart_data,␣
 ↪num_examples=0)
print(f"precision: {precision:3.2f}")
print(f"recall:    {recall:3.2f}")
print(f"F1:        {f1:3.2f}")
```

```
0it [00:00, ?it/s]332it [20:02,  3.62s/it]

precision: 0.48
recall:    0.48
F1:        0.48
```

7 Discussion

7.1 Goal 5: Compare the pros and cons of rule-based and neural approaches.

Compare the pros and cons of the rule-based approach and the neural approaches with relevant examples from your experiments above. Concerning the accuracy, which approach would you choose to be used in a product? Explain.

Comparison of Rule-Based and Neural Approaches for SQL Query Generation:

Rule-Based Approach:

Pros: - Easily understandable results. - New rules can be applied easily, even for unseen sentences without the need for training. - Results are explainable, allowing for well-needed guarantees to be provided to customers. - Systematic identification of failure points is possible, enabling explicit support through engineered rules and potential feature additions.

Cons: - Complex grammar rules can be challenging to create manually, especially for certain SQL queries. - Maintenance requires familiarity with the grammar, which can become problematic as the grammar becomes more complex or when managed by different teams.

Neural Approach:

Pros: - Self-training capability with sufficient examples, enabling the model to "understand" on its own. - Ability to decode complex rule-required sentences into the correct SQL queries.

Cons: - Lack of explainability; the model learns weights for decision-making, but the meaning behind these weights remains unclear. - Requires a substantial amount of diverse examples to achieve efficient performance.

Considering the pros and cons of the two approaches, the rule-based approach is favored for product use. The explainable results it provides allow for essential guarantees to be given to customers. By systematically identifying and addressing failure points through engineered rules, the rule-based approach allows explicit support and feature enhancements to be incorporated into the product. On the other hand, the neural approach lacks explainability, making it challenging to understand the model's decisions, which may lead to difficulties in providing the same level of assurances to customers.

8 Debrief

Question: We're interested in any thoughts you have about this project segment so that we can improve it for later years, and to inform later segments for this year. Please list any issues that arose or comments you have to improve the project segment. Useful things to comment on might include the following:

- Was the project segment clear or unclear? Which portions?
- Were the readings appropriate background for the project segment?
- Are there additions or changes you think would make the project segment better?

but you should comment on whatever aspects you found especially positive or negative.

Type your answer here, replacing this text.

9 Instructions for submission of the project segment

This project segment should be submitted to Gradescope at `https://rebrand.ly/project4-submit-code` and `https://rebrand.ly/project4-submit-pdf`, which will be made available some time before the due date.

Project segment notebooks are manually graded, not autograded using otter as labs are. (Otter is used within project segment notebooks to synchronize distribution and solution code however.) **We will not run your notebook before grading it.** Instead, we ask that you submit the already freshly run notebook. The best method is to "restart kernel and run all cells", allowing time for all cells to be run to completion. You should submit your code to Gradescope at the code submission assignment at https://rebrand.ly/project4-submit-code. Make sure that you are also submitting your `data/grammar` file as part of your solution code as well.

We also request that you **submit a PDF of the freshly run notebook**. The simplest method is to use "Export notebook to PDF", which will render the notebook to PDF via LaTeX. If that doesn't work, the method that seems to be most reliable is to export the notebook as HTML (if you are using Jupyter Notebook, you can do so using `File -> Print Preview`), open the HTML in a browser, and print it to a file. Then make sure to add the file to your git commit. Please name the file the same name as this notebook, but with a `.pdf` extension. (Conveniently, the methods just described will use that name by default.) You can then perform a git commit and push and submit the commit to Gradescope at https://rebrand.ly/project4-submit-pdf.
